Аннотация:

Using pulse acoustic microscopy the samples of bone-substitute biodegradable polymer materials were examined. It was shown at frequency range of 50-100 MHz the method is a powerful non-destructive instrument to study internal microstructure morphology and to characterize elastic property of biomaterials. Microstructure of polylactide and polyhydroxybutyrate polymer samples in the form of plates, films and non-woven fabrics were investigated. It was shown that the heating/cooling variations in technological regime affect the structure of the polymer components. The processes of porous formation for the studied biomaterials were studied by means of acoustic microscopy techniques.
